Research Project on Causes of PRP Needs Interested Patients

A research team at Jefferson Medical College in Philadelphia, Pennsylvania, is conducting a special project to examine a possible genetic connection to PRP. It is hoped the continuing research will eventually lead to knowing the underlying causes which lead to newer forms of treatment for this rare problematic condition.

The research project now seeks world-wide participants who currently have or who ever have had PRP. Following your initial indication of interest, there will be a research associate reply that provides additional project information and explains procedures. Participants will be expected to provide some personal and medical information. A small blood sample is to then be provided. Blood is to be collected at your local physician’s office, medical clinic/lab or hospital where you live and then sent to our laboratory for the research analysis. When unable to get blood drawn, a special kit provision for saliva collection has been established. Further, children under 8 years of age can have buccal cells collected. Details will be explained in our reply.

For all interested participants, please contact us for more information, specific instructions, and enrollment forms. Please initiate e-mail contact as follows:

Subject: PRP Research Participant
